## **EQUATIONS**

#### LEARNING OBJECTIVES

After studying this chapter, you will be able to:

- ◆ Understand the concept of equations and its various degrees linear, simultaneous, quadratic and cubic equations;
- ♦ Know how to solve the different equations using different methods of solution; and

Equation is defined to be a mathematical statement of equality. If the equality is true for certain value of the variable involved, the equation is often called a conditional equation and equality sign '=' is used; while if the equality is true for all values of the variable involved, the equation is called an identity.

For Example: 
$$\frac{x+2}{3} + \frac{x+3}{2} = 3$$
 holds true only for  $x = 1$ .

So it is a conditional. On the other hand, 
$$\frac{x+2}{3} + \frac{x+3}{2} = \frac{5x+13}{6}$$

is an identity since it holds for all values of the variable x.

Determination of value of the variable which satisfy an equation is called solution of the equation or root of the equation. An equation in which highest power of the variable is 1 is called a Linear (or a simple) equation. This is also called the equation of degree 1. Two or more linear equations involving two or more variables are called *Simultaneous Linear Equations*. An equation of degree 2 (Highest Power of the variable is 2) is called *Quadratic equation* and the equation of degree 3 is called *Cubic Equation*.

For Example: 
$$8x+17(x-3) = 4 (4x-9) + 12$$
 is a Linear equation.  
 $3x^2 + 5x + 6 = 0$  is a Quadratic equation.  
 $4x^3 + 3x^2 + x - 7 = 1$  is a Cubic equation.  
 $x + 2y = 1$ ,  $2x + 3y = 2$  are jointly called Simultaneous equations.

## **2.2 SIMPLE EQUATION**

A simple equation in one unknown x is in the form ax + b = 0.

Where a, b are known constants and a # 0

**Note:** A simple equation has only one root.

**Example:** 
$$\frac{4x}{3} - 1 = \frac{14}{15}x + \frac{19}{5}$$
.

**Solution:** By transposing the variables in one side and the constants in other side we have

$$\frac{4x}{3} - \frac{14x}{15} = \frac{19}{5} + 1 \text{ or } \frac{(20-14)x}{15} = \frac{19+5}{5} \text{ or } \frac{6x}{15} = \frac{24}{5}.$$

$$x = \frac{24x15}{5x6} = 12$$

#### "ILLUSTRATIONS:

1. The denominator of a fraction exceeds the numerator by 5 and if 3 be added to both the fraction becomes  $\frac{3}{4}$ . Find the fraction.

Let x be the numerator and the fraction be  $\frac{x}{x+5}$ . By the question  $\frac{x+3}{x+5+3} = \frac{3}{4}$  or 4x + 12 = 3x + 24 or x = 12

The required fraction is  $\frac{12}{17}$ .

2. If thrice of A's age 6 years ago be subtracted from twice his present age, the result would be equal to his present age. Find A's present age.

Let x years be A's present age. By the question

$$2x-3(x-6) = x$$
or 
$$2x-3x + 18 = x$$
or 
$$-x + 18 = x$$
or 
$$2x = 18$$
or 
$$x=9$$

- ∴ A's present age is 9 years.
- 3. A number consists of two digits the digit in the ten's place is twice the digit in the unit's place. If 18 be subtracted from the number the digits are reversed. Find the number.

Let x be the digit in the unit's place. So the digit in the ten's place is 2x. Thus the number becomes 10(2x) + x. By the question

$$20x + x - 18 = 10x + 2x$$
  
or  $21x - 18 = 12x$   
or  $9x = 18$   
or  $x = 2$ 

So the required number is  $10(2 \times 2) + 2 = 42$ .

4. For a certain commodity the demand equation giving demand 'd' in kg, for a price 'p' in rupees per kg. is d = 100 (10 - p). The supply equation giving the supply s in kg. for a price p in rupees per kg. is s = 75(p - 3). The market price is such at which demand equals supply. Find the market price and quantity that will be bought and sold.

Given 
$$d = 100(10 - p)$$
 and  $s = 75(p - 3)$ .

Since the market price is such that demand (d) = supply (s) we have

100 (10 - p) = 75 (p - 3) or 1000 - 100p = 75p - 225  
or - 175p = - 1225. 
$$\therefore$$
 p =  $\frac{-1225}{-175}$  = 7.

So market price of the commodity is ₹ 7 per kg.

∴ the required quantity bought = 100 (10 - 7) = 300 kg. and the quantity sold = 75 (7 - 3) = 300 kg.

## ( 2.3 SIMULTANEOUS LINEAR EQUATIONS IN TWO UNKNOWNS

The general form of a linear equations in two unknowns x and y is ax + by + c = 0 where a, b are non-zero coefficients and c is a constant. Two such equations  $a_1x + b_1y + c_1 = 0$ and  $a_1x + b_2y + c_2 = 0$  form a pair of simultaneous equations in x and y. A value for each unknown which satisfies simultaneously both the equations will give the roots of the equations.

### ( 2.4 METHOD OF SOLUTION

Elimination Method: In this method two given linear equations are reduced to a linear equation in one unknown by eliminating one of the unknowns and then solving for the other unknown.

**Example 1: Solve:** 2x + 5y = 9 and 3x - y = 5.

**Solution:** 2x + 5y = 9 ...... (i)

$$3x - y = 5$$
 .....(ii)

By making (i) x 1, 2x + 5y = 9

and by making (ii) x = 5, 15x - 5y = 25

Adding 17x = 34 or x = 2. Substituting this values of x in (i) i.e. 5y = 9 - 2x we find;

$$5y = 9 - 4 = 5$$
 :  $y = 1$  :  $x = 2$ ,  $y = 1$ .

**Cross Multiplication Method:** Let two equations be:

 $a_1x + b_1y + c_1 = 0$ 

$$a_2 x + b_2 y_+ c_2 = 0$$

We write the coefficients of x, y and constant terms and two more columns by repeating the coefficients of x and y as follows:

and the result is given by:  $\frac{x}{b_1c_2 - b_2c_1} = \frac{y}{(c_1a_2 - c_2a_1)} = \frac{1}{(a_1b_2 - a_2b_1)}$ 

so the solution is:

$$x = \frac{b_1 c_2 - b_2 c_1}{a_1 b_2 - a_2 b_1} \qquad y = \frac{c_1 a_2 - c_2 a_1}{a_1 b_2 - a_2 b_1}.$$

**Example 2:** Solve 3x + 2y + 17 = 0, 5x - 6y - 9 = 0

**Solution:** 3x + 2y + 17 = 0 ...... (i)

$$5x - 6y - 9 = 0$$
 .....(ii)

Method of elimination: By (i) x 3 we get 9x + 6y + 51 = 0 ..... (iii)

Adding (ii) & (iii) we get 14x + 42 = 0

or 
$$x = -\frac{42}{14} = -3$$

Putting x = -3 in (i) we get 3(-3) + 2y + 17 = 0

or, 
$$2y + 8 = 0$$
 or,  $y = -\frac{8}{2} = -4$ 

So 
$$x = -3$$
 and  $y = -4$ 

**Method of cross-multiplication:** 3x + 2y + 17 = 0

$$5x - 6y - 9 = 0$$

$$\frac{x}{2(-9)-17(-6)} = \frac{y}{17\times(5)-3(-9)} = \frac{1}{3(-6)-5\times(2)}$$

or, 
$$\frac{x}{84} = \frac{y}{112} = \frac{1}{-28}$$

or 
$$\frac{x}{3} = \frac{y}{4} = \frac{1}{-1}$$

or 
$$x = -3$$
,  $y = -4$ 

## 2.5 METHOD OF SOLVING SIMULTANEOUS LINEAR EQUATION WITH THREE VARIABLES

**Example 1: Solve** for x, y and z:

$$2x - y + z = 3$$
,  $x + 3y - 2z = 11$ ,  $3x - 2y + 4z = 1$ 

Solution: (a) Method of elimination

$$2x - y + z = 3$$

$$x + 3y - 2z = 11$$
 .... (ii)

$$3x - 2y + 4z = 1$$
 .... (iii)

By (i) 
$$\times$$
 2 we get

$$4x - 2y + 2z = 6$$
 .... (iv)

By (ii) + (iv), 
$$5x + y = 17$$
 ....(v) [the variable z is thus eliminated]

.....(i)

By (ii) 
$$\times$$
 2,  $2x + 6y - 4z = 22$  ....(vi)

By (iii) + (vi), 
$$5x + 4y = 23$$
 ....(vii)

By 
$$(v) - (vii)$$
,  $-3v = -6$  or  $v = 2$ 

Putting y = 2 in (v) 
$$5x + 2 = 17$$
, or  $5x = 15$  or,  $x = 3$ 

Putting 
$$x = 3$$
 and  $y = 2$  in (i)

$$2 \times 3 - 2 + z = 3$$

or 
$$6 - 2 + z = 3$$

or 
$$4 + z = 3$$

or 
$$z = -1$$

So x = 3, y = 2, z = -1 is the required solution.

(Any two of 3 equations can be chosen for elimination of one of the variables)

#### (b) Method of cross multiplication

We write the equations as follows:

$$2x - y + (z - 3) = 0$$

$$x + 3y + (-2z - 11) = 0$$

By cross multiplication

$$\frac{x}{-1(-2z-11)-3(z-3)} = \frac{y}{(z-3)-2(-2z-11)} = \frac{1}{(2\times3)-(1(-1))}$$

$$\frac{x}{20-z} = \frac{y}{5z+19} = \frac{1}{7}$$

$$x = \frac{20 - z}{7}$$
,  $y = \frac{5z + 19}{7}$ 

Substituting above values for x and y in equation (iii) i.e. 3x - 2y + yz = 1, we have

$$3\left(\frac{20-z}{7}\right) - 2 \quad \left(\frac{5z+19}{7}\right) + 4z = 1$$

or 
$$60 - 3z - 10z - 38 + 28z = 7$$

or 
$$15z = 7 - 22$$
 or  $15z = -15$  or  $z = -1$ 

Now 
$$x = \frac{20 - (-1)}{7} = \frac{21}{7} = 3$$
,  $y = \frac{5(-1) + 19}{7} = \frac{14}{7} = 2$ 

Thus 
$$x = 3$$
,  $y = 2$ ,  $z = -1$ 

**Example 2:** Solve for x, y and z:

$$\frac{1}{x} + \frac{1}{y} + \frac{1}{z} = 5$$
,  $\frac{2}{x} - \frac{3}{y} - \frac{4}{z} = -11$ ,  $\frac{3}{x} + \frac{2}{y} - \frac{1}{z} = -6$ 

**Solution:** We put  $u = \frac{1}{x}$ ;  $v = \frac{1}{y}$ ;  $w = \frac{1}{z}$  and get

$$u + v + w = 5$$
 ...... (i)

$$2u - 3v - 4w = -11....$$
 (ii)

$$3u + 2v - w = -6....$$
 (iii)

By (i) + (iii) 
$$4u + 3v = -1$$
 ...... (iv)

By (iii) 
$$\times 4$$
  $12u + 8v - 4w = -24$  ...... (v)

By (ii) – (v) 
$$-10u - 11v = 13$$

or 
$$10u + 11v = -13$$
 ...... (vi)

By (vii) – (viii) 
$$14u = 28 \text{ or } u = 2$$

Putting u = 2 in (iv) 
$$4 \times 2 + 3v = -1$$

or 
$$8 + 3v = -1$$

or 
$$3v = -9$$
 or  $v = -3$ 

Putting 
$$u = 2$$
,  $v = -3$  in (i) or  $2-3 + w = 5$ 

or 
$$-1 + w = 5$$
 or  $w = 5 + 1$  or  $w = 6$ 

Thus 
$$x = \frac{1}{u} = \frac{1}{2}$$
,  $y = -\frac{1}{v} = \frac{1}{-3}$ ,  $z = \frac{1}{w} = \frac{1}{6}$  is the solution.

**Example 3:** Solve for x, y and z:

$$\frac{xy}{x+y} = 70$$
,  $\frac{xz}{x+z} = 84$ ,  $\frac{yz}{y+z} = 140$ 

**Solution:** We can write as

$$\frac{x+y}{xy} = \frac{1}{70} \text{ or } \frac{1}{x} + \frac{1}{y} = \frac{1}{70}$$
 ..... (i)

$$\frac{x+z}{xz} = \frac{1}{84} \text{ or } \frac{1}{z} + \frac{1}{x} = \frac{1}{84}$$
 ...... (ii)

$$\frac{y+z}{vz} = \frac{1}{140}$$
 or  $\frac{1}{v} + \frac{1}{z} = \frac{1}{140}$  ..... (iii)

By (i) + (ii) + (iii), we get 
$$2\left(\frac{1}{x} + \frac{1}{y} + \frac{1}{z}\right) = \frac{1}{70} + \frac{1}{84} + \frac{1}{140} = \frac{14}{420}$$

or 
$$\frac{1}{x} + \frac{1}{y} + \frac{1}{z} = \frac{7}{420} = \frac{1}{60}$$
 .....(iv)

By (iv)-(iii) 
$$\frac{1}{x} = \frac{1}{60} - \frac{1}{140} = \frac{4}{420}$$
 or  $x = 105$ 

By (iv)-(ii) 
$$\frac{1}{y} = \frac{1}{60} - \frac{1}{84} = \frac{2}{420}$$
 or  $y = 210$ 

By (iv)-(i) 
$$\frac{1}{z} = \frac{1}{60} - \frac{1}{70}$$
 or  $z = 420$ 

Required solution is x = 105, y = 210, z = 420

- **SOLUTION:** Let x/y be the required fraction.

By the question 
$$\frac{x+2}{y+1} = 1, \frac{x-4}{y-2} = \frac{1}{2}$$

Thus 
$$x + 2 = y + 1$$
 or  $x - y = -1$  ...... (i)

and 
$$2x - 8 = y - 2$$
 or  $2x - y = 6$  ...... (ii)

or 
$$2x - y = 6$$

By (i) – (ii) – 
$$x = -7$$

or 
$$x = 7$$

from (i) 
$$7 - y = -1$$

or 
$$y = 8$$

So the required fraction is 7/8.

- The age of a man is three times the sum of the ages of his two sons and 5 years hence his 2. age will be double the sum of their ages. Find the present age of the man?
- **SOLUTION:** Let x years be the present age of the man and sum of the present ages of the two sons be y years.

By the condition

$$x = 3y$$

$$x = 3y$$
 ......(i)

and

$$x + 5 = 2 (y + 5 + 5)$$
 .....(ii)

From (i) & (ii) 
$$3y + 5 = 2(y + 10)$$

or 
$$3y + 5 = 2y + 20$$

or 
$$3y - 2y = 20 - 5$$

or 
$$y = 15$$

$$\therefore x = 3 \times y = 3 \times 15 = 45$$

Hence the present age of the man is 45 years

## **( 2.7 QUADRATIC EQUATION**

An equation of the form  $ax^2 + bx + c = 0$  where x is a variable and a, b, c are constants with a  $\neq$  0 is called a quadratic equation or equation of the second degree.

When b=0 the equation is called a pure quadratic equation; when  $b \neq 0$  the equation is called an affected quadratic.

**Examples:** 

i) 
$$2x^2 + 3x + 5 = 0$$

ii) 
$$x^2 - x = 0$$

iii) 
$$5x^2 - 6x - 3 = 0$$

The value of the variable say x is called the root of the equation. A quadratic equation has got two roots.

How to find out the roots of a quadratic equation:

$$ax^2 + bx + c = 0 \quad (a \neq 0)$$

or 
$$x^2 + \frac{b}{a}x + \frac{c}{a} = 0$$

or 
$$x^2 + 2\frac{b}{2a} x + \frac{b^2}{4a^2} = \frac{b^2}{4a^2} - \frac{c}{a}$$

or 
$$\left(x + \frac{b}{2a}\right)^2 = \frac{b^2}{4a^2} - \frac{c}{a}$$

or 
$$x + \frac{b}{2a} = \frac{\pm \sqrt{b^2 - 4ac}}{2a}$$

or 
$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Sum and Product of the Roots:

Let one root be  $\alpha$  and the other root be  $\beta$ 

Now 
$$\alpha + \beta = \frac{-b + \sqrt{b^2 - 4ac}}{2a} + \frac{-b - \sqrt{b^2 - 4ac}}{2a} = \frac{-b + \sqrt{b^2 - 4ac} - b - \sqrt{b^2 - 4ac}}{2a}$$
$$= \frac{-2b}{2a} = \frac{-b}{a}$$

Thus sum of roots = 
$$-\frac{b}{a} = -\frac{\text{coefficient of } x}{\text{coeffient of } x^2}$$

Next 
$$\alpha\beta = \left(\frac{-b + \sqrt{b^2 - 4ac}}{2a}\right) \left(\frac{-b - \sqrt{b^2 - 4ac}}{2a}\right) = \frac{c}{a}$$

So the product of the roots =  $\frac{c}{a} = \frac{\text{constant term}}{\text{coefficient of } x^2}$ 

## ( 2.8 HOW TO CONSTRUCT A QUADRATIC EQUATION

For the equation  $ax^2 + bx + c = 0$  we have

or 
$$x^2 + \frac{b}{a}x + \frac{c}{a} = 0$$

or 
$$x^2 - \left(-\frac{b}{a}\right)x + \frac{c}{a} = 0$$

or  $x^2$  – (Sum of the roots) x + Product of the roots = 0

## **( 2.9 NATURE OF THE ROOTS**

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

- If  $b^2$ –4ac = 0 the roots are real and equal;
- If  $b^2$ –4ac >0 then the roots are real and unequal (or distinct);
- If  $b^2$ –4ac <0 then the roots are imaginary;

- iv) If  $b^2$ -4ac is a perfect square ( $\neq$  0) the roots are real, rational and unequal (distinct);
- v) If  $b^2$ –4ac >0 but not a perfect square the roots are real, irrational and unequal. Since  $b^2$  – 4ac discriminates the roots  $b^2$  – 4ac is called the discriminant in the equation  $ax^2 + bx + c = 0$  as it actually discriminates between the roots.
- **Note:** (a) Irrational roots occur in conjugate pairs that is if  $(m + \sqrt{n})$  is a root then  $(m \sqrt{n})$  is the other root of the same equation.
  - (b) If one root is reciprocal to the other root then their product is 1 and so  $\frac{c}{a} = 1$  i.e. c = a
  - (c) If one root is equal to other root but opposite in sign then.

their sum = 0 and so  $\frac{b}{a}$  = 0. i.e. b = 0.

**Example 1:** Solve  $x^2 - 5x + 6 = 0$ 

**Solution:** 1st method :  $x^2 - 5x + 6 = 0$ 

or 
$$x^2 - 2x - 3x + 6 = 0$$

or 
$$x(x-2) - 3(x-2) = 0$$

or 
$$(x-2)(x-3) = 0$$

or 
$$x = 2$$
 or 3

2nd method (By formula)  $x^2 - 5x + 6 = 0$ 

Here a = 1, b = -5, c = 6 (comparing the equation with  $ax^2 + bx + c = 0$ )

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} = \frac{-(-5) \pm \sqrt{25 - 24}}{2}$$

$$=\frac{5\pm 1}{2}=\frac{6}{2}$$
 and  $\frac{4}{2}$ ;  $x = 3$  and 2

**Example 2:** Examine the nature of the roots of the following equations.

i) 
$$x^2 - 8x + 16 = 0$$

ii) 
$$3x^2 - 8x + 4 = 0$$

iii) 
$$5x^2 - 4x + 2 = 0$$

iv) 
$$2x^2 - 6x - 3 = 0$$

**Solution:** (i) a = 1, b = -8, c = 16

$$b^2 - 4ac = (-8)^2 - 4 \times 1 \times 16 = 64 - 64 = 0$$

The roots are real and equal.

(ii) 
$$3x^2 - 8x + 4 = 0$$

$$a = 3, b = -8, c = 4$$

$$b^2 - 4ac = (-8)^2 - 4 \times 3 \times 4 = 64 - 48 = 16 > 0$$
 and a perfect square

The roots are real, rational and unequal

(iii) 
$$5x^2 - 4x + 2 = 0$$
  
 $b^2 - 4ac = (-4)^2 - 4 \times 5 \times 2 = 16 - 40 = -24 < 0$ 

The roots are imaginary and unequal

(iv) 
$$2x^2 - 6x - 3 = 0$$
  
 $b^2 - 4ac = (-6)^2 - 4 \times 2 (-3)$   
 $= 36 + 24 = 60 > 0$ 

The roots are real and unequal. Since  $b^2$  – 4ac is not a perfect square the roots are real irrational and unequal.

## illustrations:

- 1. If  $\alpha$  and  $\beta$  be the roots of  $x^2 + 7x + 12 = 0$  find the equation whose roots are  $(\alpha + \beta)^2$  and  $(\alpha \beta)^2$ .
- SOLUTION: Now sum of the roots of the required equation

$$= (\alpha + \beta)^2 + (\alpha - \beta)^2 = (-7)^2 + (\alpha + \beta)^2 - 4\alpha\beta$$
$$= 49 + (-7)^2 - 4x12$$

$$= 49 + 49 - 48 = 50$$

Product of the roots of the required equation =  $(\alpha + \beta)^2 (\alpha - \beta)^2$ 

Hence the required equation is

$$x^2$$
 – (sum of the roots)  $x$  + product of the roots = 0 or  $x^2$  –  $50x$  +  $49$  = 0

2. If  $\alpha$ ,  $\beta$  be the roots of  $2x^2 - 4x - 1 = 0$  find the value of  $\frac{\alpha^2}{\beta} + \frac{\beta^2}{\alpha}$ 

**SOLUTION:** 
$$\alpha + \beta = \frac{-(-4)}{2} = 2$$
,  $\alpha\beta = \frac{-1}{2}$ 

$$\therefore \frac{\alpha^2}{\beta} + \frac{\beta^2}{\alpha} = \frac{\alpha^3 + \beta^3}{\alpha\beta} = \frac{(\alpha + \beta)^3 - 3\alpha\beta(\alpha + \beta)}{\alpha\beta}$$

$$\frac{2^3 - 3\left(-\frac{1}{2}\right) \cdot 2}{\left(-\frac{1}{2}\right)} = -22$$

3. Solve  $x: 4^x - 3.2^{x+2} + 2^5 = 0$ 

SOLUTION: 
$$4^{x} - 3.2^{x+2} + 2^{5} = 0$$
  
or  $(2^{x})^{2} - 3.2^{x}$ .  $2^{2} + 32 = 0$   
or  $(2^{x})^{2} - 12$ .  $2^{x} + 32 = 0$   
or  $y^{2} - 12y + 32 = 0$  (taking  $y = 2^{x}$ )  
or  $y^{2} - 8y - 4y + 32 = 0$   
or  $y(y - 8) - 4(y - 8) = 0$   $\therefore$   $(y - 8)(y - 4) = 0$   
either  $y - 8 = 0$  or  $y - 4 = 0$   $\therefore$   $y = 8$  or  $y = 4$ .  
 $\Rightarrow 2^{x} = 8 = 2^{3}$  or  $2^{x} = 4 = 2^{2}$  Therefore  $x = 3$  or  $x = 2$ .

4. Solve 
$$\left(x - \frac{1}{x}\right)^2 + 2\left(x + \frac{1}{x}\right) = 7\frac{1}{4}$$
.

**SOLUTION:** 
$$\left(x - \frac{1}{x}\right)^2 + 2\left(x + \frac{1}{x}\right) = 7\frac{1}{4}$$
.

$$\left(x - \frac{1}{x}\right)^2 + 2\left(x + \frac{1}{x}\right) = \frac{29}{4}.$$

or 
$$\left(x + \frac{1}{x}\right)^2 - 4 + 2\left(x + \frac{1}{x}\right) = \frac{29}{4}$$

[as 
$$(a - b)^2 = (a + b)^2 - 4ab$$
]

or 
$$p^2 + 2p^{-2} - \frac{45}{4} = 0$$
 Taking  $p = x + \frac{1}{x}$ 

or 
$$4p^2 + 8p - 45 = 0$$

or 
$$4p^2 + 18p - 10p - 45 = 0$$

or 
$$2p(2p + 9) - 5(2p + 9) = 0$$

or 
$$(2p - 5)(2p + 9) = 0$$
.

$$\therefore \text{Either } 2p + 9 = 0 \text{ or } 2p - 5 = 0 \qquad \Rightarrow p = -\frac{9}{2} \qquad \text{or } p = \frac{5}{2}$$

$$\therefore \text{Either } x + \frac{1}{x} = -\frac{9}{2} \qquad \text{or } x + \frac{1}{x} = \frac{5}{2}$$

i.e. Either 
$$2x^2 + 9x + 2 = 0$$
 or  $2x^2 - 5x + 2 = 0$ 

i.e. Either 
$$x = \frac{-9 \pm \sqrt{81-16}}{4}$$
 or,  $x = \frac{5 \pm \sqrt{25-16}}{4}$ 

i.e. Either 
$$x = \frac{-9 \pm \sqrt{65}}{4}$$
 or  $x = 2$  or  $\frac{1}{2}$ .

5. Solve 
$$2^{x-2} + 2^{3-x} = 3$$

**SOLUTION:** 
$$2^{x-2} + 2^{3-x} = 3$$

or 
$$2^x$$
.  $2^{-2} + 2^3$ .  $2^{-x} = 3$ 

or 
$$\frac{2^x}{2^2} + \frac{2^3}{2^x} = 3$$

or 
$$\frac{t}{4} + \frac{8}{t} = 3$$
 when  $t = 2^x$ 

or 
$$t^2 + 32 = 12t$$

or 
$$t^2 - 12t + 32 = 0$$

or 
$$t^2 - 8t - 4t + 32 = 0$$

or 
$$t(t-8) - 4(t-8) = 0$$

or 
$$(t-4)(t-8) = 0$$

$$\therefore t = 4, 8$$

For 
$$t = 4$$
,  $2^x = 4 = 2^2$  i.e.  $x = 2$ 

For 
$$t = 8$$
,  $2^x = 8 = 2^3$  i.e.  $x = 3$ 

**6.** If one root of the equation is  $2-\sqrt{3}$  form the equation given that the roots are irrational

**SOLUTION:** Other root is 
$$2 + \sqrt{3}$$
 : sum of two roots  $= 2 - \sqrt{3} + 2 + \sqrt{3} = 4$ 

Product of roots = 
$$(2 - \sqrt{3})(2 + \sqrt{3}) = 4 - 3 = 1$$

... Required equation is : 
$$x^2$$
 – (sum of roots) $x$  + (product of roots) = 0 or  $x^2 - 4x + 1 = 0$ .

7. If  $\alpha$   $\beta$  are the two roots of the equation  $x^2 - px + q = 0$  form the equation whose roots are  $\frac{\alpha}{\beta}$  and  $\frac{\beta}{\alpha}$ .

**SOLUTION:** As  $\alpha$ ,  $\beta$  are the roots of the equation  $x^2 - px + q = 0$ 

$$\alpha + \beta = -(-p) = p$$
 and  $\alpha \beta = q$ .

Now 
$$\frac{\alpha}{\beta} + \frac{\beta}{\alpha} = \frac{\alpha^2 + \beta^2}{\alpha\beta} = \frac{(\alpha + \beta)^2 - 2\alpha\beta}{\alpha\beta} = \frac{p^2 - 2q}{q}$$
; and  $\frac{\alpha}{\beta} \cdot \frac{\beta}{\alpha} = 1$ 

$$\therefore \text{ Required equation is } x^2 - \left(\frac{p^2 - 2q}{q}\right)x + 1 = 0$$

or 
$$q x^2 - (p^2 - 2q) x + q = 0$$

- 8. If the roots of the equation  $p(q-r)x^2 + q(r-p)x + r(p-q) = 0$  are equal show that  $\frac{2}{q} = \frac{1}{p} + \frac{1}{r}$ .
- **SOLUTION:** Since the roots of the given equation are equal the discriminant must be

zero ie. 
$$q^2(r-p)^2 - 4$$
.  $p(q-r) r(p-q) = 0$ 

or 
$$q^2 r^2 + q^2 p^2 - 2q^2 rp - 4pr (pq - pr - q^2 + qr) = 0$$

or 
$$p^2q^2 + q^2r^2 + 4p^2r^2 + 2q^2pr - 4p^2qr - 4pqr^2 = 0$$

or 
$$(pq + qr - 2rp)^2 = 0$$

$$\therefore$$
 pq + qr = 2pr

or 
$$\frac{pq+qr}{2pr} = 1$$
 or,  $\frac{q}{2} \cdot \frac{(p+r)}{pr} = 1$  or,  $\frac{1}{r} + \frac{1}{p} = \frac{2}{q}$

## ( 2.10 PROBLEMS ON QUADRATIC EQUATION

Difference between a number and its positive square root is 12; find the numbers? **Solution:** Let the number be *x*.

Then  $x - \sqrt{x} = 12$  .....(i)

$$(\sqrt{x})^2 - \sqrt{x} - 12 = 0.$$
 Taking  $y = \sqrt{x}$ ,  $y^2 - y - 12 = 0$ 

or 
$$(y-4)(y+3) = 0$$
 : Either  $y = 4$  or  $y = -3$  i.e. Either  $\sqrt{x} = 4$  or  $\sqrt{x} = -3$ 

If  $\sqrt{x} = -3 x = 9$  if does not satisfy equation (i) so  $\sqrt{x} = 4$  or x = 16.

A piece of iron rod costs ₹ 60. If the rod was 2 metre shorter and each metre costs ₹ 1.00 more, the cost would remain unchanged. What is the length of the rod?

**Solution:** Let the length of the rod be x metres. The rate per meter is  $\frac{60}{x}$ .

New Length = (x - 2); as the cost remain the same the new rate per meter is  $\frac{60}{x-2}$ 

As given 
$$\frac{60}{x-2} = \frac{60}{x} + 1$$

or 
$$\frac{60}{x-2} - \frac{60}{x} = 1$$

or 
$$\frac{120}{x(x-2)} = 1$$

or 
$$x^2 - 2x = 120$$

or 
$$x^2 - 2x - 120 = 0$$
 or  $(x - 12)(x + 10) = 0$ .

Either x = 12 or x = -10 (not possible)

 $\therefore$  Hence the required length = 12m.

Divide 25 into two parts so that sum of their reciprocals is 1/6.

**Solution:** let the parts be x and 25 - x

By the question 
$$\frac{1}{x} + \frac{1}{25-x} = \frac{1}{6}$$

or 
$$\frac{25-x+x}{x(25-x)} = \frac{1}{6}$$

or 
$$150 = 25x - x^2$$

or 
$$x^2-25x+150 = 0$$
  
or  $x^2-15x-10x+150 = 0$   
or  $x(x-15) - 10(x-15) = 0$   
or  $(x-15) (x-10) = 0$   
or  $x = 10, 15$ 

	So the parts of 2	5 are 10 and 15.

## ( 2.11 SOLUTION OF CUBIC EQUATION

On trial basis putting if some value of x stratifies the equation then we get a factor. This is a trial and error method. With this factor to factorise the LHS and then other get values of x.

Solve  $x^3 - 7x + 6 = 0$ 

Putting x = 1 L.H.S is Zero. So (x-1) is a factor of  $x^3 - 7x + 6$ 

We write  $x^3-7x+6=0$  in such a way that (x-1) becomes its factor. This can be achieved by writing the equation in the following form.

or 
$$x^3 - x^2 + x^2 - x - 6x + 6 = 0$$

or 
$$x^2(x-1) + x(x-1) - 6(x-1) = 0$$

or 
$$(x-1)(x^2+x-6) = 0$$

or 
$$(x-1)(x^2+3x-2x-6) = 0$$

or 
$$(x-1)\{x(x+3) - 2(x+3)\} = 0$$

or 
$$(x-1)(x-2)(x+3) = 0$$

 $\therefore$  or x = 1, 2, -3

- Solve for real x:  $x^3 + x + 2 = 0$
- **SOLUTION:** By trial we find that x = -1 makes the LHS zero. So (x + 1) is a factor of  $x^3 + x + 2$

We write  $x^3 + x + 2 = 0$  as  $x^3 + x^2 - x^2 - x + 2x + 2 = 0$ 

or 
$$x^2(x + 1) - x(x + 1) + 2(x + 1) = 0$$

or 
$$(x + 1)(x^2 - x + 2) = 0$$
.

Either x + 1 = 0; x = -1

or 
$$x^2 - x + 2 = 0$$
 i.e.  $x = -1$ 

i.e. 
$$x = \frac{1 \pm \sqrt{1-8}}{2} = \frac{1 \pm \sqrt{-7}}{2}$$

As  $x = \frac{1 \pm \sqrt{-7}}{2}$  is not real, x = -1 is the required solution.

#### SUMMARY

• A simple equation in one unknown x is in the form ax + b = 0.

Where a, b are known constants and  $a \neq 0$ 

- ♦ The general form of a linear equations in two unknowns x and y is ax + by + c = 0 where a, b are non-zero coefficients and c is a constant. Two such equations  $a_1x + b_1y + c_1 = 0$  and  $a_2x + b_2y + c_2 = 0$  form a pair of simultaneous equations in x and y. A value for each unknown which satisfies simultaneously both the equations will give the roots of the equations.
- Elimination Method: In this method two given linear equations are reduced to a linear
  equation in one unknown by eliminating one of the unknowns and then solving for the
  other unknown.
- Cross Multiplication Method: Let two equations be:

$$a_1 x + b_1 y + c_1 = 0$$

$$a_2 x + b_2 y_+ c_2 = 0$$

$$x = \frac{b_1 c_2 - b_2 c_1}{a_1 b_2 - a_2 b_1} \qquad y = \frac{c_1 a_2 - c_2 a_1}{a_1 b_2 - a_2 b_1}.$$

• An equation of the form  $ax^2 + bx + c = 0$  where x is a variable and a, b, c are constants with a  $^1$  0 is called a quadratic equation or equation of the second degree.

When b=0 the equation is called a pure quadratic equation; when b=0 the equation is called an affected quadratic.

• The roots of a quadratic equation:

$$= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

♦ The Sum and Product of the Roots of quadratic equation

sum of roots = 
$$-\frac{b}{a} = -\frac{\text{coefficient of } x}{\text{coeffient of } x^2}$$

product of the roots = 
$$\frac{c}{a} = \frac{\text{constant term}}{\text{coefficient of } x^2}$$

- To construct a quadratic equation for the equation  $ax^2 + bx + c = 0$  we have  $x^2$  (Sum of the roots) x + Product of the roots = 0
- Nature of the roots

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

- i) If  $b^2$ –4ac = 0 the roots are real and equal;
- ii) If  $b^2$ –4ac >0 then the roots are real and unequal (or distinct);
- iii) If b2-4ac <0 then the roots are imaginary;
- iv) If  $b^2$ –4ac is a perfect square ( $\neq$  0) the roots are real, rational and unequal (distinct);
- v) If  $b^2$ –4ac >0 but not a perfect square the rots are real, irrational and unequal.

Since  $b^2$  – 4ac discriminates the roots  $b^2$  – 4ac is called the discriminant in the equation  $ax^2 + bx + c = 0$  as it actually discriminates between the roots.
